Project Description (est. 1 page, pt. 5)

Literature Review(est. 1 page, pt.10)

Summary Statistics and Data Preprocessing (est. 1-2 pages, pt.10)

Data Overview

The dataset has 705 observations and 1941 features (1936 predictors and 5 outcomes). There are four different kinds of predictors: rs (gene expression), cn (copy number variations), mu (mutations), and pp (protein levels). Among them, rs and pp are continuous variables, and cn and mu are categorical variables.

Remove Missing Values

According to the instruction, we dropped vital.status, and we only considered each response variable as a binary variable. Therefore, we treated the observations that had other outcomes as missing values and removed them from our dataset.

Then the dataset sub had 507 observations and 1940 features.

[1] 507 1940

Deal with Multicollinearity

One of the noticeable characteristics of the data is its high dimensionality. There are 1936 predictors, almost four times as many as there are observations. Therefore, it is essential to check correlation.

Since there are four kinds of predictors, it is unlikely that two variables that belong to different kinds would be highly correlated. Also, to reduce the computational cost, we split the data into four subsets: rs, cn, mu, and pp, each of which contained only ond kind of predictors.

Then, we created the correlation matrix for each subset, and extracted variables that are highly-correlated with at least one other variable. Take rs as an example. The dataframe idx stores all matrix indices of highly-correlated variables and the corresponding correlation coefficients. If the i-th variable is highly-correlated with the j-th variable, then we only need one of them. Thus, we removed all variables with indices i. For rs, 94 predictors were removed. We applied the same process to the other three subsets. In total, 882 predictors were removed. There are 1059 predictors remained.

```
names(idx) = c("i", "j", "corr")
idx[1:3,]

## i j corr
## 2 3 4 0.94
## 3 5 56 0.84
## 4 9 10 0.95

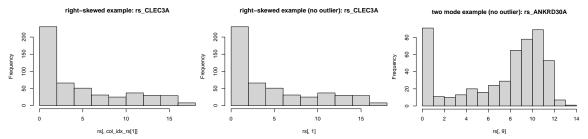

# remove highly-correlated variables
rmv = unique(idx[,1])
length(rmv)

## [1] 94
rs = rs[,-rmv]
```

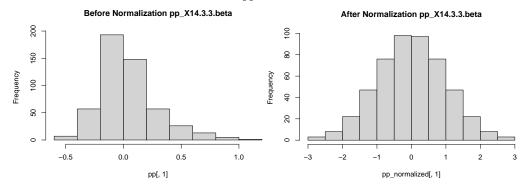

Continuous Variables

As mentioned before, rs and pp are continuous variables, so we should examine if there are any outliers. We first normalized the variable, and stored row and column indices if the data point was three standard deviations away from the variable mean. For the two subsets, rs had 100 outliers, and pp had no outlier.

We further looked into rs predictors that included outliers, and we found the vast majority of them had a long tail, mostly right and some left. In addition, a number of rs predictors that did not contain outliers also had a non-standard distribution. As a result, a log transformation of rs predictors would be beneficial.

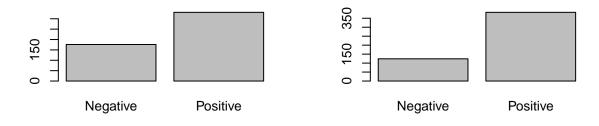

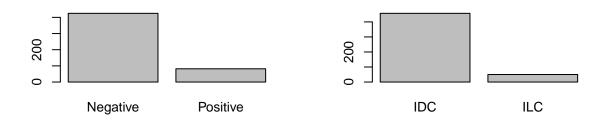

Unlike rs, pp variables were distributed quite normally. However, many of the variables would contain outliers without normalization. Therefore, we normalized pp variables.

Categorical Variables

```
par(mfrow=c(2, 2))
barplot(table(sub$PR.Status))
barplot(table(sub$ER.Status))
barplot(table(sub$HER2.Final.Status))
barplot(table(sub$histological.type), names.arg = c("IDC", "ILC"))
```

Modeling PR Status (est. 2-3 pages, pt.20)

Before modeling, we split the train and test datasets. We used 25% of the samples (126) for testing and 75% of the samples for trianing (381).

Support Vector Machine (SVM)

The goal of the project was to make classifications. Plus, we needed to deal with high-dimensional data. Therefore, we should choose classification models that perform well for high-dimensional data. Support vector machines are famous for its capability in high-dimensional spaces, so we first fitted a basic linear SVM, with the default cost = 1 to see how it worked.

As the confusion matrix showed, the in-sample accuracy was 1.0, which implies that we may prefer the linear kernel to the radial kernel.

```
## actual
## predicted Negative Positive
## Negative 133 0
## Positive 0 248
```

Then we constructed two grids of tuning parameters for both linear and radial kernels, and we used 5-fold cross-validation to tune the parameters and to determine which kernel was better.

For the linear kernel, the best C was 0.001 with an in-sample accuracy of 0.8324.

```
## C
## 1 0.001

## C Accuracy Kappa AccuracySD KappaSD
## 1 0.001 0.8336029 0.6058770 0.02730027 0.06541415
## 2 0.010 0.7999388 0.5464954 0.02526173 0.06257166
## 3 0.050 0.8014261 0.5503720 0.02442031 0.06150767
## 4 0.100 0.8014261 0.5503720 0.02442031 0.06150767
```

```
## 5 0.500 0.8014261 0.5503720 0.02442031 0.06150767
## 6 1.000 0.8014261 0.5503720 0.02442031 0.06150767
```

For the radial kernel, the best C was 0.001 and the best sigma was 3. However, the results showed that the radial SVM fitted poorly, since the accuracies remained the same and were merely 0.6677. The fact verified our hypothesis that a linear kernel would work better. Thus, we picked the linear SVM with C equals 0.001 to make classifications.

```

                                                     0
```

We made predictions for the test data, and printed the confusion table below. The accuracy was 0.9048. Thus, the linear SVM performed quite well.

```
## actual
## predicted Negative Positive
## Negative 33 2
## Positive 10 81
## [1] 0.9047619
```

Random Forest

Random forests are another classification model that is less vulnerable to "the curse of dimensionality". Since there were many parameters that needed to be tuned, we again utilized caret package to cross validate the model.

In a 5-fold cross-validation, we tuned mtry and min.node.size. In addition, we found that num.trees was also influential to both the parameter tuning and the test accuracy. Thus, we manually tuned the number of trees and chose the best value by looking at the test accuracy. The output showed that the best parameters were mtry = 40 and min.node.size = 15 when num.trees = 1000 according to the test accuracy.

```

Histological Type (hcluster and knn regression) (est 2-3 pages, pt.20)

To establish the Modeling for histological, We first use logistical regression, However, when we build the model, we found that the logistic model's algorhrim is not coverge. The reason that this error occur, because the variable x can divide the reponse variable y into 0 and 1 perfectly. The accurate will be 100%. To solve the problem we decided to use penalized regression. Thus, we choose the model of logistic regession with ridge penalty

Logistic Regression

To performance

```
y = as.factor(sub$histological.type)

y = as.factor(ifelse(y == "infiltrating lobular carcinoma", 1, 0))
sub3 = cbind(rs, cn, mu, pp, y) # cleaned dataset with PR.status as response

set.seed(651978735)
n = dim(sub)[1]
test_size = as.integer(0.25 * n)
test_idx = sample(1:n, test_size) # 25% of the sample size

Xtest = sub3[test_idx, -ncol(sub2)]
Xtrain = sub3[-test_idx, ncol(sub2)]
ytest = sub3[test_idx, ncol(sub2)]
ytrain = sub3[-test_idx, ncol(sub2)]
```
